Abstract

Polystyrene coated TiO$_2$ particles were prepared by free radical polymerization. Microcapsules containing polystyrene coated TiO$_2$ and tetrachloroethylene were synthesized via complex coacervation using gelatin and sodium alginate as wall material. The obtained particles and microcapsules were characterized by Contact angle measurement, optical microscope, scanning electron microscopy (SEM) and thermogravimetric analysis, and the results showed the surface behavior of polystyrene/ TiO$_2$ had been changed to hydrophobic and the wall of microcapsules was compacted and formed from volatile nano-size thread. Electrophoretic display prototype was prepared by coating microcapsules slurry on ITO glass and sealed by UV curable adhesive. The picture was display at a low voltage 3V D.C.

1 Introduction

Electrophoretic displays (EPD), which are one of the most promising display techniques, have attracted a great deal of academic and commercial interests because of the advantages of both electronic displays and conventional paper. They have attributes of flexibility, good contrast ratio, wide-angle view, state bistability, low power consumption. The functioning of EPD is based on the movement of colored pigments inside a colored or transparent liquid when a voltage is applied. Joseph Jacobson first reported a new model of electrophoretic ink, based on microcapsulating the electrophoretic suspension into individual microcapsules [1]. It reduced the unwilling particle movement such as particle clustering and agglomeration on a scale larger than the microcapsule size.

Electrophoretic ink microcapsules can be produced by in-situ polymerization [2-6], interfacial polymerization [7] and complex coacervation [8, 9]. Coacervation has been classified into simple and complex processes depending on the number of participating macromolecules. Veis describes complex coacervation is a two-step process with spontaneous aggregation as a result of interaction of the oppositely charged polyelectrolytes, followed by rearrangement of these aggregates into coacervate phase[10]. Gelatin, zwitterionic macromolecule, is one of the most important wall materials in production of microcapsules. Sodium alginate is linear and anionic polysaccharide, which can interact with positively charged gelatin below the isoelectric point. Both of them are biodegradable, biocompatible and have a natural surface activity. In this study, we adopted complex coacervation technology to prepare gelatin/alginate microcapsules containing tetrachloroethylene and polystyrene coated TiO$_2$. Furthermore, electrophoretic display prototype was prepared by coating a slurry containing microcapsules on ITO glass and sealed by UV curable adhesive.

2 Experimental

2.1 Encapsulation of modified TiO$_2$ by polystyrene via free radical polymerization

We followed the procedure reported by Yu Rong to prepare polystyrene coated TiO$_2$ [10].

5g TiO$_2$ was dispersed in 150mL ethanol by ultrasonic for 1h, then 3.1g γ-methacryloxypropyltrimethoxysilane (MPS), 6.5g water, 3.4g ammonia (25wt.%) were added. The mixture was under ultrasonic for 1h and stirred at room temperature for 48 hours. Next, filtered and dried.

1.5g TiO$_2$ modified by MPS was dispersed in 50g ethanol in flask fitted with a condenser, then 4.5g styrene monomer and 0.3g AIBN were added. Polymerization was performed at 70°C in the nitrogen atmosphere for 24h.

2.2 Preparation of gelatin/Alginate microcapsules

30g of tetrachloroethylene dyed by oil red or oil blue was dispersed at 45°C in 100g of sodium alginate aqueous solution (1wt.%). The equal amount of 1wt.% gelatin aqueous solution at 45°C was then added into the above solution and adjust pH close to 5.0 with continue stirring. The addition of acetic acid solution induced the complex coacervation for 5h. Next, temperature of the mixture cooled to 5-10°C slowly with continued vigorous stirring. 25wt.% Glutaraldehyde and 5wt.% CaCl$_2$ solution was added dropwise for crosslinking the microcapsules. The microcapsules were studied in preparation medium without further treatment.

2.3 Preparation of electrophoretic display prototype

Slurry containing electrophoretic ink microcapsules was coated on ITO glass with nearly single layer, then drying for 3h at 80°C, finally sealed by UV curable adhesives.

3 Results and discussion

3.1 Investigation of polystyrene/ TiO$_2$ by free radical polymerization

Yu Rong reported that dispersion stability of electrophoretic suspension depends not only on the density matching between polymer/pigment particles and solvent, but also on the steric stabilization[11]. TiO$_2$ is commonly used due to its high refractive index and excellent whiteness. However, the density of TiO$_2$ (rutile) is 4.26g/cm$^3$ which much higher than most of solvent. Encapsulation of TiO$_2$ by polystyrene can reduce the density mismatch between...
pigments and solvent. On the other hand, polymer coated TiO$_2$ prevented the particles depart from electrophoretic suspension to water phase during complex coacervation process.

Contact angle measurement was used to research the change of surface behavior of particles. The contact angle of TiO$_2$ and Polystyrene/ TiO$_2$ is 0° and 130.3° respectively. It was demonstrated that the surface behavior of polystyrene/ TiO$_2$ had been changed to hydrophobic.

3. 2 characterization of gelatin/alginate microcapsule

3.2.1 Particle size characteristics of gelatin/Alginate microcapsules

At the beginning of experiment, electrophoretic suspension was separate by mechanical agitation to small droplets. Gelatin and sodium alginate were adsorbed at the O/W surface due to their natural surface activity. The adsorption is not only available for stability of droplets, but also prerequisite for coacervation.

If pigments particles are evenly dispersed in solvent, the average microcapsule diameter is controlled by the agitation rate as shown in Fig.1. When the agitation rate increases, the average diameter descends.

3.2.2 Effect of weight ratio of core to wall materials

As shown in Figure 2, as the weight ratio of core to wall materials increases, the wall thickness of microcapsules descends.

When the ratio is 10:1, microcapsules become spindly due to excess of wall materials. Since microcapsules use to break at the thinnest spot, spherical microcapsules are more stable than spindly microcapsules.

3.2.3 Surface morphology of gelatin/alginate microcapsule

The surface morphology and microstructure of dried microcapsules have been studied by means of SEM. Figure 3a show the surface of microcapsule is smooth. When the distance between microcapsules was close enough, they usually extrude each other and turn to pentagonal or hexagonal instead of spherical as shown in Figure 3b. It indicates the wall of microcapsules is elastic, which is of advantage to prepare single and compact layer on ITO glass. Fig.3c and 3d depicts cross-section of microcapsule. We can find the wall of microcapsule has compact microstructure, and suggests that the walls are formed from voluble nano-size thread.

3.2.4 Stability of gelatin/alginate microcapsules

Figure 4 shows the changes of gelatin/alginate microcapsules weight as a function of heating temperature. The weight loss of
microcapsules is 9.27% below 215.2 °C, which correspond to desorption of small molecules such as H₂O on the surface of microcapsules and a little release of tetrachloroethylene. There is a dramatic weight loss at the range of 215.2-270.1 °C, which indicating most of microcapsules were broken and tetrachloroethylene has been released. Since the range of temperature is much higher than the boiling point of tetrachloroethylene (121 °C), we can conclude that microcapsules have good thermal property.

Furthermore, gelatin/alginate microcapsules, reserved in water for more than one year at room temperature, have the same electrophoretic property as new products.

3.3 Electrophoretic display prototype

Gelatin/alginate microcapsules coated on ITO glass were compactly conterminal each other due to the elastic wall. The phenomenon increased the contrast of prototype and area of display. The picture was displayed at low volt of 3V D.C as shown in Fig 5, which was much lower than displays made by Satoshi Inoue (18V)[12] and arrived at request of commercial use.

4 Conclusions

Polystyrene coated TiO₂ particles were prepared by free radical polymerization. Contact angle measurement showed that the surface behavior of polystyrene/ TiO₂ had been changed to hydrophobic. Gelatin/alginate Microcapsules containing PS/ TiO₂ and tetrachloroethylene were synthesized via complex coacervation. The average microcapsule diameter was controlled by the agitation rate. As the weight ratio of core to wall materials increases, the wall thickness of microcapsules descends. SEM showed the wall of microcapsule has compact microstructure, and suggests that the walls are formed from voluble nano-size thread. Thermogram of gelatin/alginate microcapsules indicates that they have good thermal property.
